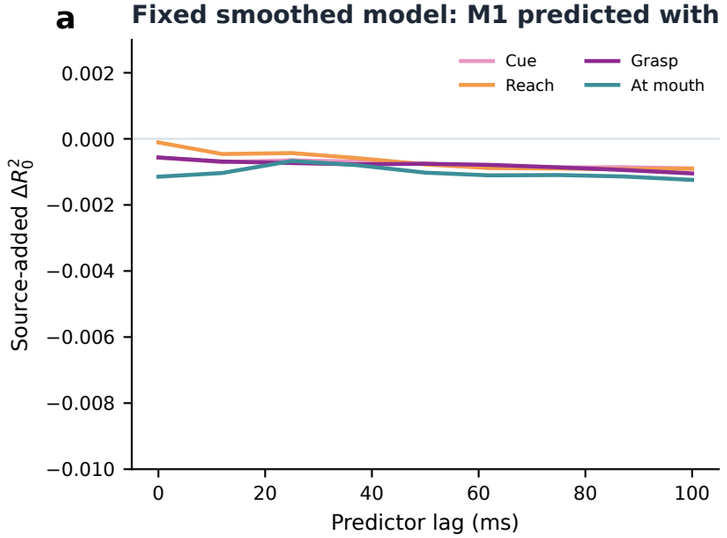
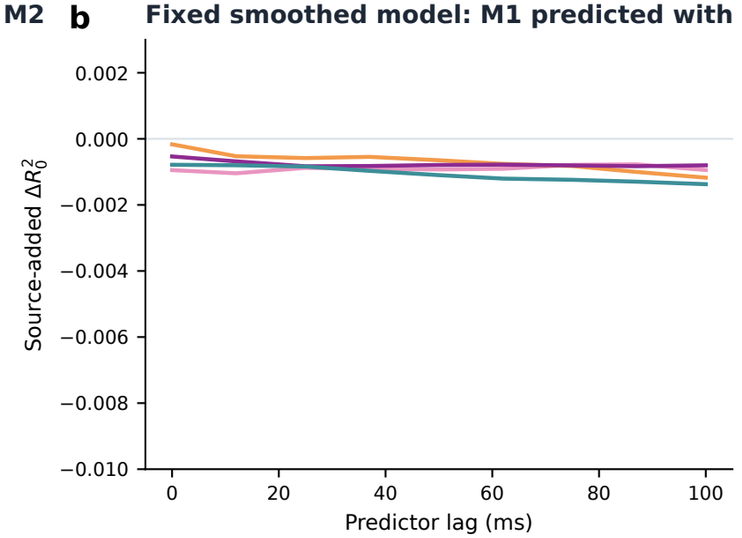
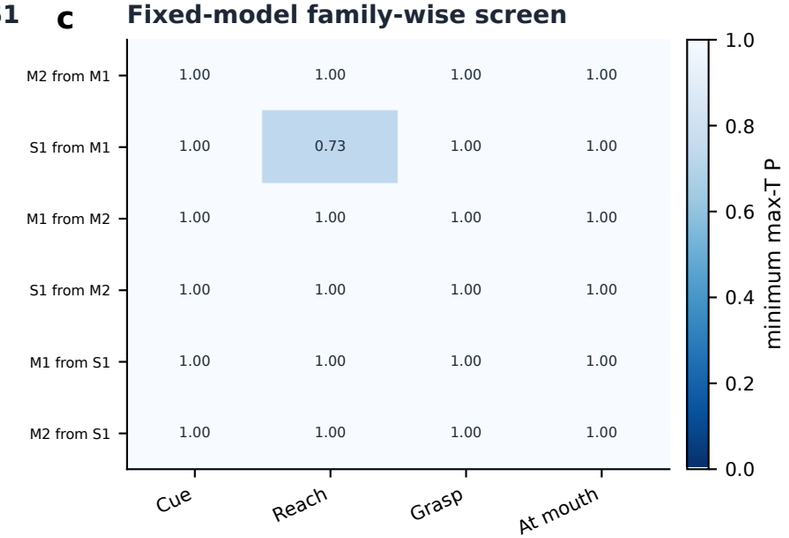
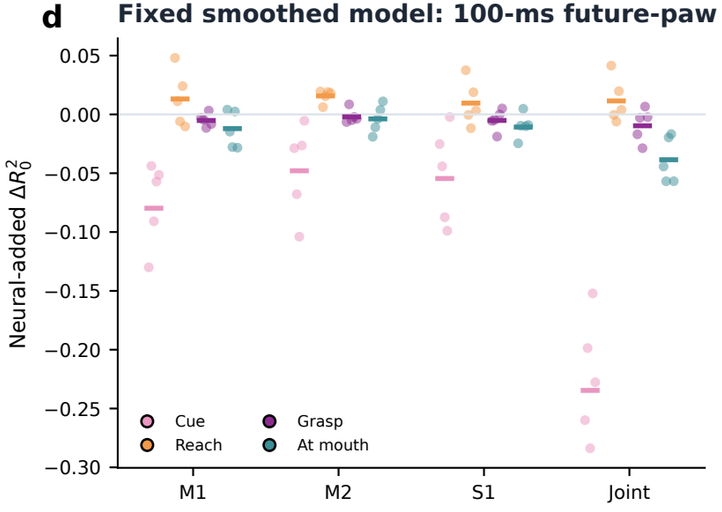
Extended Data Figure 7 | Fixed-model screens delimit the conditional mapping claim









e What remains

Observed

Event-specific instantaneous predictive mappings

Fixed-model screen

No corrected evidence of improved future-target prediction

No corrected evidence of improved 100-ms paw prediction

f Physiological claim boundary

Can say	conditional prediction differs across movement events
Cannot say	M2 or S1 drives M1
Cannot say	feedback loop is causal
Next experiment	simultaneous perturbation + independent mice

One mouse/day. Fixed-ridge models use symmetrically smoothed neural features; there is no corrected evidence of improvement in these screens. They cannot establish absence of direction or behavior information and are not fine-lag direction estimates.
