Extended Data Figure 10b | A recurrent encoder-sensitive backbone is reused across factors and phases

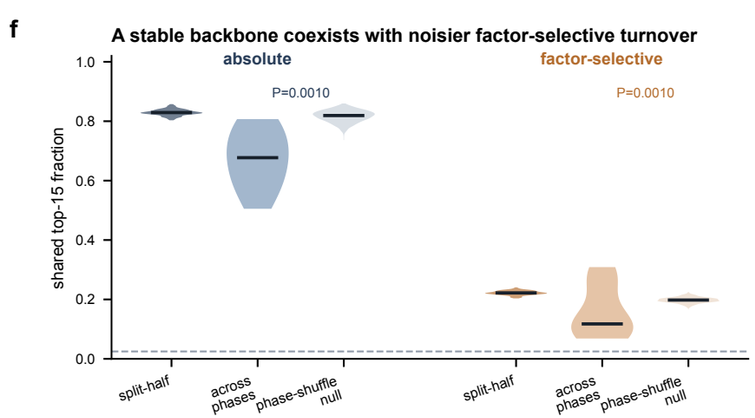

Absolute top sets preserve global encoder sensitivity; factor-selective sets subtract each neuron's within-phase mean log effect across all 38 factors. Null sets preserve area × within-area training-rate-quintile composition. Whole-trial deletion is evaluated within each phase window; n=9 trials and weak factor-selective split-half reliability prohibit stable single-cell or causal claims.
