Extended Data Figure 2a | Sign-constrained baseline-modulation curves

Each robust curve is anchored at (0,0): the red branch is non-negative and the blue branch non-positive, so the two fits cannot cross.

Independent trial halves estimate baseline and cue modulation. The sign-preserving model is y = +/-a log(1 + baseline/tau), with positive a and tau fit by robust soft-L1 loss. Source data report five-fold RMSE and bootstrap amplitude intervals. This descriptive fit does not imply that baseline firing causes cue modulation.
