Extended Data Figure 2b | The apparent double bump reflects mixed peak latencies

Narrow templates peak near 0.2 ms and wide templates near 0.6 ms; no strict-QC template contains two independently resolved post-trough peaks under the prespecified criterion.

a, Trough-aligned class medians and interquartile bands show distinct early and late post-peaks. b, Every strict-QC cluster is placed by trough-to-peak duration and post-peak/trough ratio. A separate exported per-template peak test found no waveform meeting the prespecified dual-peak criterion; the omitted summary bar is therefore not needed for interpretation.
