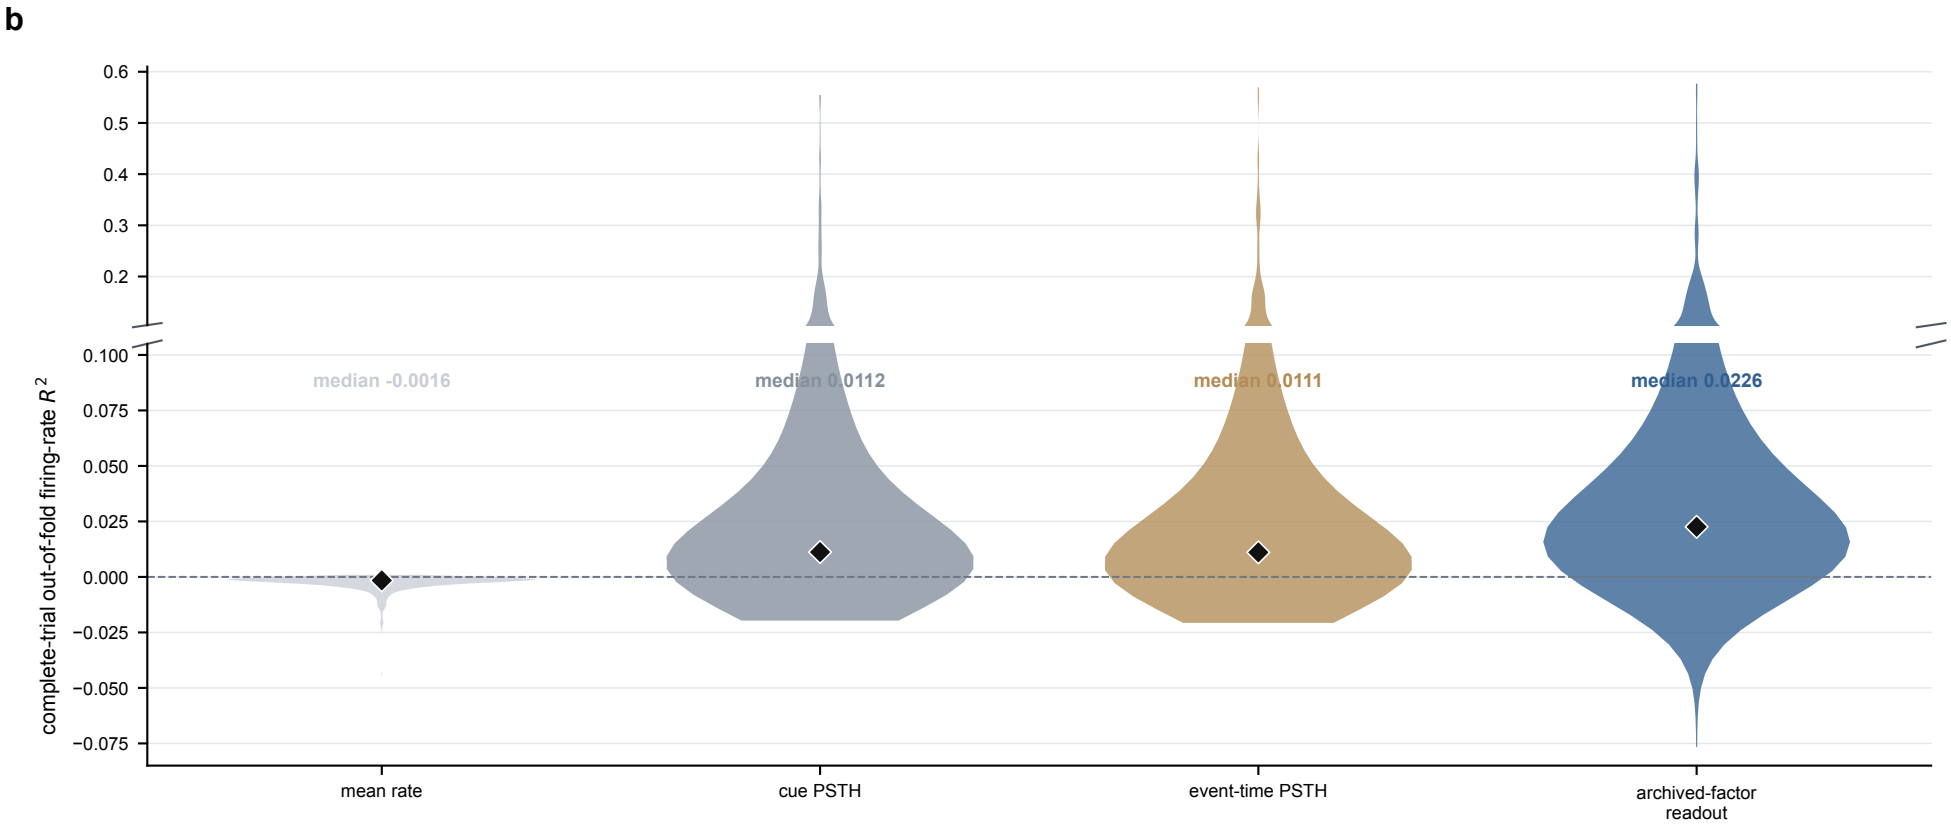

Figure 8b | Archived factors improve population-wide held-out reconstruction

A broken y-axis enlarges the central distributions while retaining every neuron's high-R² tail; diamonds are medians.

Every one of the 603 strict-QC neurons contributes a complete-trial out-of-fold R² for the mean-rate, cue-PSTH, event-time-PSTH and archived-factor downstream readouts. The full untrimmed values are plotted on both axis segments. Absolute spike-level R² remains modest even though the archived-factor median exceeds the template baselines.
